

COVID-19 and HIV

(updated January 2023)

COVID-19 and HIV

This educational packet is a curated compilation of resources on COVID-19 and HIV.

The contents of this packet are listed below:

- [HIV and COVID-19 Basics \(CDC\)](#)
- [COVID-19 and People with HIV \(HIV.gov\)](#)
- [What You Can do if You Are at Higher Risk of Severe Illness from COVID-19 \(CDC\)](#)
- [Guidance for COVID-19 and People with HIV \(Clinicalinfo.HIV.gov\)](#)

You may wish to customize this packet to meet the needs or interests of particular groups, such as event participants, providers, patients, clients, or the general public. So please feel free to distribute all or part of this document as either a printout or PDF.

HIV and COVID-19 Basics

 cdc.gov/hiv/basics/covid-19.html

July 12, 2022

People with HIV may have concerns and questions about COVID-19, including the risk of serious illness and vaccine safety. CDC will continue to provide updated information as it becomes available.

Are people with HIV at higher risk for serious illness from COVID-19 than other people?

We are still learning about COVID-19 and how it affects people with HIV. Nearly half of people in the United States with diagnosed HIV are ages 50 and older. People with HIV also have higher rates of certain underlying health conditions. Older age and underlying health conditions can make people more likely to become seriously ill if they get COVID-19. This is especially true for people with advanced HIV or people with HIV who are not on treatment.

People at increased risk for severe illness, and those who live with or visit them, should take precautions (including getting vaccinated and wearing a well-fitting mask) to protect themselves and others from COVID-19.

Do COVID-19 treatments interact with medicine to treat or prevent HIV?

Some COVID-19 treatments can interact with antiretroviral therapy (ART) used to treat HIV. If you have HIV, let your health care provider know before starting COVID-19 treatment. There are no known interactions between HIV treatment and the medicine used to prevent COVID-19 (Evusheld).

For people without HIV, there is no evidence that currently available medicine used to treat or prevent COVID-19 will interact with pre-exposure prophylaxis (PrEP) to prevent HIV.

If you have possible symptoms of COVID-19, have had a positive test, or been exposed to the virus that causes COVID-19, talk to your health care provider to see if you're eligible for COVID-19 treatment or preventive medicine.

Do COVID-19 vaccines increase the risk of someone getting HIV?

No. There is no association between COVID-19 vaccines and risk for HIV infection. COVID-19 vaccines improve the immune system's ability to prevent COVID-19 and protect vaccinated people from the more severe complications of COVID-19.

Are COVID-19 vaccines safe for people with HIV?

Yes. COVID-19 vaccines are safe for people with HIV. COVID-19 vaccines meet the Food and Drug Administration's rigorous scientific standards for safety, effectiveness, and manufacturing quality and people with HIV were included in vaccine clinical trials.

Authorized or approved COVID-19 vaccines will continue to undergo the most intensive safety monitoring. This includes using established and new safety monitoring systems to make sure that COVID-19 vaccines are safe.

Find a COVID-19 vaccine or booster: Search [vaccines.gov](https://www.vaccines.gov), text your ZIP code to 438829, or call 1-800-232-0233 to find locations near you.

Learn more about what CDC and other federal agencies are doing to make sure COVID-19 vaccines are safe and effective.

How many doses of the COVID-19 vaccine do people with HIV need to get?

COVID-19 Vaccine Primary Series

COVID-19 vaccines are recommended for everyone who is eligible. The number of vaccine doses you need depends on the type of vaccine you receive.

Additional Primary Shot

After completing the COVID-19 vaccine primary series, some people who have advanced HIV (including an AIDS diagnosis) or who have HIV and are not taking HIV treatment should get an additional primary shot. The additional primary shot is intended to improve a person's immune response to their two-dose COVID-19 vaccine primary series. People who are eligible for an additional primary shot should receive this dose before they get a booster shot. Talk to your health care provider to determine if getting an additional primary shot is right for you.

CDC **does not** recommend an additional primary shot of the COVID-19 vaccine for people with HIV who are virally suppressed or who do not have advanced HIV.

Booster Shot

CDC recommends that everyone, including people with HIV, get a booster shot when they are eligible. Learn more about who should get a booster, when to get a booster, and which booster you should get.

Find a COVID-19 vaccine or booster: Search [vaccines.gov](https://www.vaccines.gov), text your ZIP code to 438829, or call 1-800-232-0233 to find locations near you.

Will COVID-19 vaccines interfere with medicine to prevent or treat HIV?

There is no evidence that COVID-19 vaccines interfere with pre-exposure prophylaxis (PrEP) to prevent HIV or with antiretroviral therapy (ART) to treat HIV. Learn more about the different COVID-19 vaccines.

What can people with HIV do to protect themselves from COVID-19?

People with HIV can protect themselves from COVID-19 by following CDC's COVID-19 prevention recommendations.

If you have HIV and are taking your HIV medicine as prescribed, it is important to continue your treatment and follow your health care provider's advice. This is the best way to keep your immune system healthy. People with HIV should also continue to maintain a healthy lifestyle.

Here are more steps that people with HIV can take:

- Make sure you have at least a 30-day (or longer) supply of your HIV medicine and any other medicines or medical supplies you need for managing HIV. Ask your health care provider about getting your medicine by mail.
- Talk to your health care provider and make sure all your vaccinations are up to date, including vaccinations against seasonal influenza (flu) and bacterial pneumonia. These vaccine-preventable diseases affect people with HIV more than others.
- When possible, keep your medical appointments. Check with your health care provider about safety precautions for office visits and ask about telemedicine or remote clinical care options.
- People with HIV can sometimes be more likely than others to need extra help from friends, family, neighbors, community health workers, and others. If you become sick, make sure you stay in touch by phone or email with people who can help you.

What should I do if I think I might have COVID-19?

Call your health care provider if you develop symptoms that could be consistent with COVID-19.

It's important to continue taking your HIV medicine as prescribed. This will help keep your immune system healthy.

Learn more about COVID-19 and what to do if you get sick.

Can HIV medicine (ART) be used to treat COVID-19?

Currently, treatment for COVID-19 is limited. There are no HIV medicines approved to treat COVID-19. People with HIV should not switch their HIV medicine in an attempt to prevent or treat COVID-19.

Some clinical trials are looking at whether HIV medicines can treat COVID-19. Other trials are looking at the effectiveness of different drugs to treat COVID-19 in people with HIV. They are also looking to better understand how people with HIV manage COVID-19. You can learn more at [ClinicalTrials.gov](https://clinicaltrials.gov).

Should people with HIV travel at this time?

Everyone, including people with HIV, should follow [CDC's COVID-19 travel](#) recommendations.

What can everyone do to minimize stigma about COVID-19?

Minimizing stigma and misinformation about COVID-19 is very important. People with HIV have experience in dealing with stigma and can be allies in preventing COVID-19 stigma. Learn how you can [reduce stigma and help prevent the spread of rumors](#) about COVID-19.

COVID-19 and People with HIV

 hiv.gov/hiv-basics/staying-in-hiv-care/other-related-health-issues/coronavirus-covid-19

How Does COVID-19 Affect People with HIV?

We are still learning about COVID-19 and how it affects people with HIV. Nearly half of people in the United States with diagnosed HIV are ages 50 and older. People with HIV also have higher rates of certain underlying health conditions. Older age and underlying medical conditions can make people more likely to get very sick if they get COVID-19. This is especially true for people with advanced HIV or people with HIV who are not on treatment.

People at increased risk for severe illness, and those who live with or visit them, should take precautions (including getting vaccinated and wearing a well-fitting mask) to protect themselves and others from COVID-19.

Visit [COVID-19 and HIV FAQs from CDC](#) for the latest information.

Feeling sick? Call your health care provider if you develop symptoms that could be consistent with COVID-19. **Keep taking your HIV medicine as prescribed.** This will help keep your immune system healthy. If you are not taking HIV medicine, talk to your health care provider about the benefits of getting on HIV treatment. Learn more about what to do if you get sick.

COVID-19 Treatment. If you test positive and are more likely to get very sick from COVID-19,, talk to your health care provider to see if you're eligible for COVID-19 treatment or preventive medicine that can reduce your chances of being hospitalized or dying from the disease. You can also visit a Test to Treat location and, if eligible, receive a prescription from a provider. Don't delay: COVID-19 treatment must be started within the first few days to be effective. But be aware: **some COVID-19 treatments can interact with antiretroviral therapy (ART) used to treat HIV.** If you have HIV, let your health care provider know before starting COVID-19 treatment. However, there are no known interactions between ART and the medicine used to *prevent* COVID-19 (Evusheld). For people without HIV, there is also no evidence that currently available medicine used to prevent or treat COVID-19 will interact with pre-exposure prophylaxis (PrEP) to prevent HIV.

COVID-19 Vaccines and People with HIV

Get vaccinated. COVID-19 vaccines are recommended for everyone ages 6 months and older including people with HIV, regardless of their CD4 count or viral load. The number of vaccine doses you need depends on your age and the type of vaccine you receive.

Additional primary shot. After completing the COVID-19 vaccine primary series, some people who have advanced HIV (including an AIDS diagnosis) or who have HIV and are not taking HIV treatment should get an additional primary shot. This additional primary shot is intended to improve a person's immune response to their two-dose COVID-19 vaccine primary series. People who are eligible for this additional primary shot should receive this dose before they get a booster shot. **CDC does not recommend** an additional primary shot of the COVID-19 vaccine for people with HIV who are virally suppressed or who do not have advanced HIV. Talk to your health care provider to determine if getting an additional primary shot is right for you.

Booster shots. Booster shots are an important part of protecting yourself from getting seriously ill or dying from COVID-19. CDC recommends that everyone, including people with HIV, get a booster shot when they are eligible. **CDC recommends that everyone over age 5 get one updated (bivalent) booster if it has been more than 2 months since your last dose. If you've had COVID-19, CDC says you may delay getting your booster by 3 months since your symptoms ended.** Use CDC's COVID-19 booster tool to learn when to get a booster and which booster you should get.

Vaccine safety. COVID-19 vaccines are safe for people with HIV. COVID-19 vaccines meet the Food and Drug Administration's rigorous scientific standards for safety, effectiveness, and manufacturing quality and people with HIV were included in vaccine clinical trials.

There is no evidence that COVID-19 vaccines interfere with ART or with pre-exposure prophylaxis (PrEP) to prevent HIV. Learn more about vaccine safety.

If you have questions about getting COVID-19 vaccine and whether it is right for you, talk to your health care provider.

WHAT YOU CAN DO IF YOU ARE AT HIGHER RISK OF SEVERE ILLNESS FROM COVID-19

Are you at higher risk for severe illness?

Based on what we know now, people who are at higher risk for severe illness from COVID-19 include:

- Older adults

People of any age with the following:

- Cancer
- Chronic kidney disease
- Chronic liver disease
- Chronic lung diseases
- Cystic fibrosis
- Dementia or other neurological conditions
- Diabetes (type 1 or type 2)
- Disabilities
- Heart conditions
- HIV infection
- Immunocompromised state (weakened immune system)
- Mental health conditions
- Overweight and obesity
- Physical inactivity
- Pregnancy
- Sickle cell disease or thalassemia
- Smoking, current or former
- Solid organ or blood stem cell transplant
- Stroke or cerebrovascular disease
- Substance use disorders
- Tuberculosis

Here's what you can do to help protect yourself:

Stay up to date with COVID-19 vaccines

Wear a well-fitting mask when recommended

Avoid crowds and poorly ventilated spaces

If you have symptoms, test soon and treat early

Wash your hands often

Monitor your health daily

Call your healthcare professional if you are sick. For more information on steps you can take to protect yourself, see CDC's [How to Protect Yourself](#).

[cdc.gov/coronavirus](https://www.cdc.gov/coronavirus)

Guidance for COVID-19 and People with HIV

 clinicalinfo.hiv.gov/en/guidelines/guidance-covid-19-and-people-hiv/guidance-covid-19-and-people-hiv

Feb. 22, 2022

This guidance reviews special considerations regarding COVID-19 for people with HIV and their health care providers in the United States. Information and data on COVID-19 are rapidly evolving. Clinicians should refer to updated sources for more specific recommendations regarding prevention, diagnosis, and treatment of COVID-19, including the National Institutes of Health (NIH) [COVID-19 Treatment Guidelines](#), which has a section on [Special Considerations in People with HIV](#).

Whether people with HIV are at greater risk of acquiring SARS-CoV-2 infection is currently unknown. Data are emerging on the clinical outcomes of COVID-19 in people with HIV. In some of the initial case series of people with COVID-19 in Europe and the United States, no significant differences were observed in the clinical outcomes of COVID-19 between people with HIV and people who did not have HIV.¹⁻¹⁰ In contrast, more recent reports suggest worse outcomes for patients with HIV and COVID-19, including high COVID-19 mortality rates in cohort studies from the United States, the United Kingdom, and South Africa.¹¹⁻¹⁸ HIV was independently associated with an increased risk of severe and critical COVID-19 in a large trial from the World Health Organization's Global Clinical Platform that included data from 24 countries.¹¹ In a multicenter cohort study of 286 patients with HIV and COVID-19 in the United States, lower CD4 T lymphocyte (CD4) cell counts (i.e., <200 cells/mm³) were associated with a higher risk for the composite endpoint of intensive care unit (ICU) admission, invasive mechanical ventilation, or death. This increased risk was observed even in patients who had achieved virologic suppression of HIV.¹² In a large observational cohort study of people with HIV and COVID-19 in the United States, those with CD4 counts <350 cells/mm³ were more likely to be hospitalized, require ventilation, or die. Higher levels of viremia were also associated with worse clinical outcomes.¹³ In another study of 175 patients with HIV and COVID-19, a low CD4 count or a low CD4 nadir was associated with poor clinical outcomes.¹⁴ In a cohort study conducted in New York, people with HIV and COVID-19 had higher rates of hospitalization and mortality than people with COVID-19 who did not have HIV.¹⁵

In the general population, individuals who are at highest risk of severe COVID-19 include those older than 60 years; those who are pregnant; solid organ or hematologic transplant recipients; and those with comorbidities—such as obesity, diabetes mellitus, cardiovascular disease, liver disease (especially cirrhosis), chronic kidney disease, pulmonary disease, cancer, smoking history, and sickle cell disease.¹⁹ Many people with HIV have one or more comorbidities that may put them at increased risk for a more severe course of COVID-19. Both COVID-19 and HIV disproportionately affect communities of color.

Guidance for All People with HIV

- People with HIV should follow all applicable recommendations of the Centers for Disease Control and Prevention (CDC) to prevent acquisition of SARS-CoV-2, such as practicing social or physical distancing, wearing masks consistently, avoiding crowded areas, and using proper hand hygiene **(AIII)**.
- People with HIV who have COVID-19 should be clinically managed in the same way as people in the general population with COVID-19, including when making medical care triage determinations **(AIII)**.
- People with HIV should receive the full series of a COVID-19 vaccine, regardless of CD4 count or viral load, because the potential benefits outweigh potential risks **(AIII)**.
 - People with HIV were included in clinical trials of the three COVID-19 vaccines available through approval or emergency use authorization (EUA) by the U.S. Food and Drug Administration (FDA).²⁰⁻²² At this time, the safety and efficacy of these vaccines in people with HIV have not been fully reported. Preliminary data in people with HIV who have received COVID-19 vaccines indicate good responses in those well controlled on antiretroviral therapy (ART) with normal CD4 counts, but diminished responses in those with advanced or untreated HIV infection.²³⁻²⁵ Guidance for these vaccines, including for people with HIV, is available through the Advisory Committee on Immunization Practices (ACIP) and from the Infectious Diseases Society of America.
 - People with HIV also should receive booster doses of COVID-19 vaccines as recommended by the ACIP.
 - The CDC, the American College of Obstetricians and Gynecologists, and the Society of Maternal Fetal Medicine now recommend that all pregnant persons, lactating individuals, and those planning pregnancy be vaccinated against COVID-19.²⁶ The CDC also provides information about COVID-19 vaccines while pregnant or breastfeeding.
- In December 2021, the FDA issued an EUA for the combination of tixagevimab with cilgavimab for pre-exposure prophylaxis (PrEP) in certain adults and children (≥12 years and weighing at least 40 kg) who are at risk for severe COVID-19. This EUA included people with advanced or untreated HIV infection (i.e., people with CD4 counts <200 cells/mm³, history of an AIDS-defining illness without immune reconstitution, or clinical manifestations of symptomatic HIV); see the FDA's Fact Sheet for Health Care Providers for more information.
- Although bamlanivimab plus etesevimab and casirivimab plus imdevimab—two anti-SARS-CoV-2 monoclonal antibodies (mAbs) combinations—have received FDA EUA for post-exposure prophylaxis, the Guidelines Working Groups of the NIH Office of AIDS Research Advisory Council (the Panels) recommend against their use, including for people with HIV, because the Omicron variant is currently the predominant variant circulating in the United States and is not susceptible to these anti-SARS-CoV-2 mAbs **(AIII)**.

- Influenza and pneumococcal vaccinations should be kept up to date. These vaccines, as well as other vaccines, can be administered with COVID-19 vaccines during the same health care visit **(AIII)**.

General Management Considerations in People with HIV

Although some antiretroviral (ARV) agents (e.g., lopinavir/ritonavir, boosted darunavir, tenofovir disoproxil fumarate/emtricitabine) have been evaluated in clinical trials to treat or prevent COVID-19, at this time, no ARV agents have been shown to be effective in these settings.^{27,28} People with HIV should not switch their ARV regimens or add ARV drugs to their regimens for the purpose of preventing or treating SARS-CoV-2 infection **(AIII)**.

When there is substantial community transmission of SARS-CoV-2—

- Health care providers should make every effort to ensure that people with HIV maintain an adequate supply of ART and all other concomitant medications **(AIII)**. This may include exploring options for alternative delivery, such as changing the delivery of medications to mail order, when possible.
- If an ARV regimen switch is planned for reasons other than toxicities or virologic failure, the switch should be done when close follow-up and monitoring are possible **(AIII)**.

Clinic or Laboratory Monitoring Visits Related to HIV Care

When there is substantial community transmission of SARS-CoV-2—

- Together with their health care providers, people with HIV should weigh the risks and benefits of attending versus not attending in-person HIV-related clinic appointments. Factors to consider include the extent of local COVID-19 transmission, health needs that will be addressed during the appointment, HIV status (e.g., CD4 count, HIV viral load), interval since last laboratory testing, need for vaccinations, and overall health.
- Telephone or virtual visits for routine or non-urgent care and adherence counseling may replace face-to-face encounters.

People with HIV in Opioid Treatment Programs

Clinicians caring for people with HIV who are enrolled in opioid treatment programs (OTPs) should refer to the Substance Abuse and Mental Health Service Administration's [updated guidance](#) on avoiding treatment interruptions during the COVID-19 pandemic. State methadone agencies also are responsible for regulating OTPs in their jurisdictions and may provide additional guidance.

Guidance for People with HIV in Self-Isolation or Quarantine Due to SARS-CoV-2 Exposure

- Instruct patients to contact their health care providers to report that they are self-isolating or in quarantine.
- Verify that patients have adequate supplies of all medications, and expedite additional drug refills as needed.
- Devise a plan to evaluate patients if they develop COVID-19–related symptoms, including for possible transfer to a health care facility for COVID-19–related care.

Guidance for People with HIV Who Have Signs and Symptoms Consistent with or Documented SARS-CoV-2 Infection

- Clinicians should consult [CDC recommendations](#) as well as state and local health department guidance on infection control, triage, and diagnosis of SARS-CoV-2 infection, and the NIH [COVID-19 Treatment Guidelines](#) for therapeutic management of non-hospitalized or hospitalized patients with COVID-19.
- Patients should be advised to follow CDC recommendations regarding [symptoms of COVID-19](#) and call their health care providers for medical advice if they develop a fever and symptoms (e.g., cough, dyspnea). New onset or worsening dyspnea warrants in-person evaluation.
- Patients should call their clinic in advance before presenting to the care providers.
- Patients should always use respiratory, hand hygiene, and cough etiquette when presenting to a health care facility, and they should wear a face mask.
- Upon arrival to a health care facility, patients should alert registration staff of their symptoms if they have not called in advance, so that measures can be taken to prevent COVID-19 transmission in the health care setting. Specific clinic actions include placing a mask on the patient and rapidly putting the patient in a room (if available, a negative-pressure room) or other space separated from people.

Guidance for Managing People with HIV and COVID-19

Guidance When Hospitalization Is Not Necessary

- Advise patients to manage symptoms at home with supportive care for symptomatic relief. Patients should maintain close communication with their health care provider and report if symptoms progress (e.g., sustained fever for >2 days, new shortness of breath). Patients and/or caregivers should be aware of warning signs and symptoms that warrant in-person evaluation, such as new dyspnea, chest pain/tightness, confusion, or other mental status changes.
- Non-hospitalized people with HIV who have mild-to-moderate COVID-19 may be eligible to receive one of the following treatment options: ritonavir-boosted nirmatrelvir, sotrovimab, remdesivir (3 days as outpatient), bebtelovimab, or molnupiravir. Priority should be given to those with advanced HIV infection (defined as people with CD4 counts <200 cells/mm³, history of an AIDS-defining illness without immune reconstitution, or clinical manifestations of symptomatic HIV) **(AIII)**.²⁹

- People with HIV who are on a ritonavir- or cobicistat-based ARV regimen and are prescribed a 5-day course of ritonavir-boosted nirmatrelvir for the treatment of COVID-19 should continue to take their ARV regimen as prescribed without dosage alteration or interruption.
- Continue ARV regimens and other medications as prescribed.

Guidance When the Person with HIV Is Hospitalized

- ART should be continued. If the ARV drugs are not on the hospital's formulary, administer medications from the patient's home supplies.
- ARV drug substitutions **should be avoided**. If necessary, clinicians may refer to recommendations in the [Appendix C: Antiretroviral Medications that Can Be Switched Temporarily Due to Supply Shortage](#) section of the U.S. Department of Health and Human Services (HHS) [Guidelines for Caring for Persons with HIV in Disaster Areas](#).
- If patients are receiving long-acting injectable cabotegravir and rilpivirine as their ARV regimen and are due for their next dose during hospitalization, clinicians should arrange with the patient's hospital provider to continue administration of these medications without interruption. If interruptions cannot be avoided, oral forms of these agents or alternate oral ART should be made available for planned missed doses.
- If patients receive ibalizumab intravenous infusion every 2 weeks as part of their ARV regimen, clinicians should arrange with the patient's hospital provider to continue administration of this medication without interruption.
- If patients are taking an investigational ARV medication as part of their regimen, arrangements should be made with the investigational study team to continue the medication if possible.
- For critically ill patients who require tube feeding, some ARV medications are available in liquid formulations, and some pills may be crushed. The [Oral Antiretroviral/HCV DAA Administration](#)³⁰ provides information on crushing pills and formulating liquid ARV drugs. Additional information also may be available in drug product labels. Clinicians should consult an HIV specialist and/or pharmacist to assess the best way for a patient with a feeding tube to continue an effective ARV regimen.

Guidance Regarding Approved, Investigational, or Off-Label Treatment for COVID-19

- The treatment of COVID-19 in people with HIV is the same as that for people without HIV (**AIII**). The therapeutic management strategies for treating COVID-19 are evolving rapidly; clinicians should consult the NIH [COVID-19 Treatment Guidelines](#) for treatment recommendations for COVID-19 based on disease severity.
- For patients with HIV receiving COVID-19 treatment, clinicians must assess the potential for drug interactions between the COVID-19 treatment and the patient's ARV therapy and other medications. Information on potential drug interactions may be found on product labels and in [drug interaction resources](#), clinical trial protocols, or investigator brochures.

- When available, and if indicated, clinicians may consider enrolling patients with HIV in a clinical trial evaluating the safety and efficacy of an experimental treatment for COVID-19. People with HIV should not be excluded from consideration for these trials. [gov](#) is a useful resource for finding studies investigating potential treatments for COVID-19.

Additional Guidance for HIV Clinicians

- Some Medicaid and Medicare programs, commercial health insurers, and AIDS Drug Assistance Programs (ADAPs) have restrictions that prevent patients from obtaining a 90-day supply of ARV drugs and other medications. During the COVID-19 pandemic, clinicians should ask insurers/programs to waive drug-supply quantity restrictions. ADAPs also should provide patients with a 90-day supply of medications.
- People with HIV may need additional assistance with food, housing, transportation, and childcare during times of crisis and economic fragility. To enhance care engagement and continuity of ARV therapy, clinicians should make every attempt to assess their patients' need for additional social assistance and connect them with resources, including navigator services, when possible.
- During this pandemic, social distancing and isolation may exacerbate mental health and substance use issues for some persons with HIV. Clinicians should assess and address these patients' concerns and arrange additional consultations, preferably virtually, as needed.
- When there is substantial community transmission of SARS-CoV-2 in the area, telehealth options, including telephone or video calls, should be considered for routine visits and to triage visits for patients who are ill.
- Reports indicate that some measures designed to control the spread of COVID-19 may increase the risk of intimate partner violence and/or child abuse, as well as limit the ability of people to distance themselves from abusers or to access external support.^{31,32} Health care providers should assess patient safety at each clinical encounter, either in person or via telemedicine, being cognizant of the patient's ability to speak privately.
- During the COVID-19 pandemic, reproductive desires and pregnancy planning should be discussed with all people of childbearing potential. This discussion should include information on what is known and not known about COVID-19 during pregnancy. Pre-pregnancy discussions should be patient centered and should include the option to defer efforts to conceive until after the peak of the pandemic and/or more is known about the effect of COVID-19 during pregnancy. Individuals may be at increased risk of unintended pregnancy when stay-at-home measures are in effect, and continuation or initiation of appropriate contraception should be addressed, including emergency contraception. Based on clinical trial data, use of intrauterine devices and contraceptive implants beyond the expiration date specified on a package insert may be considered.³³ Depot-medroxyprogesterone acetate also may be considered for subcutaneous self-injection.

Special Considerations for Pregnancy, HIV, and COVID-19

COVID-19 and Pregnancy

- Pregnant or recently pregnant individuals are at a higher risk for severe illness and death from COVID-19 than non-pregnant individuals.
- Pregnant individuals with COVID-19 are at a higher risk for more severe infections, ICU admissions, extracorporeal membrane oxygenation, and death than individuals who are not infected with COVID-19.^{34,35} COVID-19–associated deaths among pregnant individuals increased when the Delta variant became predominant compared with the pre-Delta variant period.³⁶
- In a retrospective analysis from a single institution, the proportion of pregnant women with severe COVID-19 was higher during the period the Delta variant was predominant than during the pre-Delta variant period.³⁷
- In a population-based cohort study of pregnant women with COVID-19 in South Africa, mortality was higher among pregnant women with COVID-19 than among pregnant women without COVID-19; maternal tuberculosis, but not HIV coinfection or other comorbidities, was associated with admission for COVID-19.³⁸
- Pregnant individuals with severe COVID-19 experience more adverse outcomes—such as venous thromboembolism, increased requirement for cesarean delivery, hypertensive disorders of pregnancy, and preterm birth—than pregnant individuals with COVID-19 who are asymptomatic.
- Given the severity of COVID-19 in pregnant or recently pregnant individuals, **the Panels strongly recommend COVID-19 vaccines for pregnant and lactating individuals, as well as for those planning pregnancy.**
- As in the overall population, a disproportionately high rate of COVID-19 exists among pregnant women of color compared with pregnant White women, and possibly a higher rate of COVID-19 severity among pregnant women of color than among pregnant White women.³⁹⁻⁴²
- Emerging data indicate that COVID-19 diagnosis is associated with an increased risk for stillbirth, with a stronger association during the period the Delta variant was predominant than during the pre-Delta variant period.⁴³
- Emergency cesarean delivery and preterm delivery (28–36 weeks gestation) appear to be higher in pregnant individuals with COVID-19 than in pregnant individuals without COVID-19.
- A high rate of ICU admission in neonates exposed to SARS-CoV-2 has been seen; however, this trend is primarily due to complications of prematurity or known exposure, and most neonates do well.⁴⁴⁻⁴⁶
- Transmission of SARS-CoV-2 from mother to infant appears to be very uncommon; neonatal infection appears to occur postnatally, in most cases.^{46,47}

COVID-19, Pregnancy, and HIV

- Currently, data on pregnancy and maternal outcomes in individuals who have COVID-19 and HIV are limited.
- Pregnant individuals with HIV who have COVID-19 should be clinically managed in the same way as pregnant individuals without HIV who have COVID-19, including when making medical care triage determinations and decisions about vaccination and treatment. COVID-19 treatment and vaccination should not be withheld from pregnant individuals with HIV; see the joint statement by the [American College of Obstetricians and Gynecologists and the Society of Maternal Fetal Medicine](#).
- Pregnant individuals with HIV admitted for COVID-19 should continue their ARV regimen. Clinicians should consult with an HIV expert if any changes in ARV regimens are needed for individuals not virally suppressed.

Children with HIV

Knowledge to date about COVID-19 in children and in children with HIV can be summarized as follows:

- Minimal data exist on COVID-19 among children with HIV infection. One report from South Africa of 159 children with COVID-19 included two children with HIV.⁴⁸ Although both children with HIV were hospitalized, only one was symptomatic, and neither died. HIV infection did not seem to contribute to more severe COVID-19.⁴⁹ Like the adult population, children and adolescents of color have disproportionately higher rates of COVID-19 and hospitalization.⁵⁰
- Children appear less likely to become severely ill with COVID-19 than adults.⁵¹⁻⁵⁴
- Some subpopulations of children at higher risk for more severe COVID-19 may exist: younger age (younger than 12 months), obesity, underlying pulmonary or cardiac pathology or neurologic disease, and immunocompromising conditions are associated with more severe outcomes.⁵⁵⁻⁵⁸
- A [multisystem inflammatory syndrome in children \(MIS-C\)](#) presenting with hyperinflammatory shock, with features of Kawasaki disease and toxic shock syndrome, is associated with SARS-CoV-2. The syndrome usually occurs 2 to 4 weeks or more following infection. More than 6,400 cases have been reported in the United States alone, with more than 50 MIS-C-related deaths as of January 2022. The children have serologic evidence of infection but may not have a positive nasopharyngeal reverse transcription-polymerase chain reaction test result.⁵⁹⁻⁶¹ Children can present with diverse signs and symptoms, including fever and gastrointestinal symptoms; significantly elevated markers of inflammation; and, in severe cases, myocarditis and cardiogenic shock. Children with MIS-C tend to be older (mean age 8–9 years) than in classic Kawasaki disease (peak incidence at age 10 months).⁶²⁻⁶⁵

- Infants and children with HIV should be current on all immunizations, including influenza and pneumococcal vaccines. For additional information on vaccines, refer to [Preventing Vaccine-Preventable Diseases in Children and Adolescents with HIV Infection](#) and [Figure 1. Recommended Immunization Schedule for Children with HIV Infection Aged 0 through 18 Years; United States, 2019](#) in the Guidelines for the Prevention and Treatment of Opportunistic Infections in HIV-Exposed and HIV-Infected Children.
- During the pandemic, guidance for ART management and clinic or laboratory monitoring visits related to HIV care in children with HIV should follow the guidance outlined above (see the General Management Considerations in People with HIV and Clinic or Laboratory Monitoring Visits Related to HIV Care sections).

Recommendations in the Guidance for All People with HIV section above are applicable for children with HIV. Additional considerations include the following:

- Children with HIV who are eligible should receive COVID-19 vaccines, regardless of CD4 count or viral load. Approvals, authorizations, and vaccine dosing differ by age group and vaccine manufacturer. COVID-19 is a rapidly evolving situation, and updates will be posted as new data become available. For expedient updates on COVID-19 vaccine indications and dosing by age group, health care providers should refer to the CDC's [Interim Clinical Considerations for Use of COVID-19 Vaccines Currently Approved or Authorized in the United States](#).
- Remdesivir is FDA approved for the treatment of COVID-19 in children aged ≥ 12 years and weighing at least 40 kg, and it is available under an FDA EUA for children aged < 12 years and weighing ≥ 3.5 kg.
- Children with HIV and COVID-19 should be managed in the same manner as children who do not have HIV. For more information, health care providers should refer to [Special Considerations in Children](#) in the NIH COVID-19 Treatment Guidelines.
- There are limited data on the use of anti-SARS-CoV-2 mAbs in children and youth. Some mAbs are available through FDA EUA for PrEP and post-exposure prophylaxis against COVID-19 in infants and children with HIV. Updated guidance based on variants in circulation should be sought before use. Priority should be given to those with advanced HIV infection and/or those with other underlying conditions that increase risk of severe COVID-19.
- FDA review and CDC guidance on eligibility and indications for anti-SARS-CoV-2 mAbs continue to evolve. Health care providers should refer to the FDA and CDC websites for expedient updates.

More information regarding ARV management in adult, pregnant, and pediatric patients, as well as recommendations for prophylaxis and treatment of specific opportunistic infections, can be found in the [Clinical Guidelines](#) for HIV/AIDS.
